AB Patients with **rheumatoid arthritis** are at risk of increased prevalence of **coronary heart disease**. In general, the plasma level of high density lipoprotein cholesterol (HDL) correlates with the risk of incidence of ischemic heart disease. The levels of total, HDL, low density (LDL) cholesterol, and triglycerides were measured in sera of patients with **rheumatoid arthritis** and in healthy controls. In patients with **rheumatoid arthritis** (26 men and 103 women), the serum total and LDL cholesterol were higher, whereas the HDL cholesterol and triglycerides were lower (p less than 0.001) compared to the values observed in controls (625 men and 749 women). Similar patterns were seen when results of age and sex matched controls were compared to the results of patients suffering from **rheumatoid arthritis**. The lipid parameters of patients with **rheumatoid arthritis** were not different when the patients were treated with steroidal or nonsteroidal anti-inflammatory drugs.

 AB Recent epidemiological studies have suggested that joint **risk** factors occur for **rheumatoid arthritis** (RA) and **coronary heart disease**. We studied serum cholesterol concentration for its association with the incidence of RA in 28 362 men and 24 444 women free from arthritis at baseline. During a mean follow-up of 21 yr, 161 men and 351 women developed RA. Of these incident cases, 119 men and 229 women were rheumatoid factor (RF) positive. The serum cholesterol concentration was directly proportional to the **risk** of RF-positive RA among women and RF-negative RA among men; the age-adjusted relative risks (95% confidence intervals) per S.D. (1.4 mM/l) of the cholesterol distribution were 1.20 (1.05-1.38) and 1.56 (1.15-2.10), respectively. No association was observed, however, for RF-negative RA among women or RF-positive RA among men. The results suggest that a still unknown factor closely associated with serum cholesterol may be involved in the aetiology of RA, but complex interactions with sex and RF status seem to occur.

AB Fe in the serum of 35 normal men and 35 normal women averaged 181 ± 25 and 135 ± 21 $\gamma\%$, resp., while the av. for 21 male and 46 female **rheumatoid arthritis** patients was 113 ± 30 and 100 ± 26 , resp. The total Fe-binding capacity in 42 patients was normal. Intravenous injections of 200 mg. Fe saccharate was cleared within 24 hrs. in 17 patients but 72 hrs. were required for clearance in 7 normal controls. **Serum bilirubin** (I) of the controls but not of the patients was increased. No difference in responses to injection of a dextran-Fe complex (II) was seen in 7 controls and 17 patients but the clearance time was increased. Serum I did not change after II. No stainable Fe was found in the bone marrow of 4 of 20 male and 11 of 29 female patients. No relation between the amt. of Fe in the marrow and in the plasma was found. The abnormal Fe metabolism does not appear to be directly or wholly connected with the anemia but some relationship exists.
